

# Master Prompt — Complete GitHub Profile

Banner · Stats cards · Contribution snake · Social badges. One prompt, four phases.

**Read this first.** This prompt builds a banner in *this style* using *your* photo — it will not reproduce anyone else's. The portrait is the output of a Python pipeline (dithering, background segmentation, trajectory matching) run against one specific image. Two people running this get two different banners, which is the point. Expect real back-and-forth on contrast and crop; the first attempt rarely lands.

**You need:** a Claude session with **code execution enabled** (Python + Pillow/NumPy/SciPy), one clear photo, reference images for any real logos, a GitHub account, and a free Vercel account. Budget 1–2 hours including iteration.

## Choosing your photo — read before prompting

This determines the result more than anything in the prompt itself.

- **Flat, uniform background** — a plain wall or studio backdrop. This is what allows clean background removal for dark mode. A busy background is the single biggest cause of a poor result.
- **Clear separation** from the backdrop — don't wear a wall-coloured shirt.
- **Even lighting on the face.** Harsh shadows survive dithering and read as blotches.
- **Head-and-shoulders framing**, sharp, 1000px+ on the short edge.

### ▼ THE PROMPT — copy everything from here to "END OF PROMPT" ▼

Build my complete animated GitHub profile — banner, stats cards, contribution snake, and social badges. I've attached my photo and logo references. Work through the four phases below **in order**, and check in with me after each one. Don't generate five variations at once; show me one and let me react.

#### My details

- Name: [NAME] · GitHub username: [username] (profile repo is `username/username`, branch `main`)
- Role: [e.g. Full-Stack Developer]
- Location: [City, Country] · Education: [degree]
- Status: [e.g. Building + Learning + Shipping]
- ToolChain: [e.g. VS Code, Git, Android Studio, Figma]
- Languages: [...] · Frontend: [...] · Backend: [...] · Database: [...] · Infra: [...]
- LinkedIn [url] · Instagram [url] · Facebook [url] · Email [addr] · Portfolio [url or "coming soon"]
- Three logos to morph between: [e.g. Flutter, a `</>` glyph, Vercel] — I'm attaching reference images; **trace them, don't hand-draw them**

- Palette: portrait `[#A78BFA dark / #7C3AED light]` · UI chrome `[#22D3EE / #0891B2]` · accent `[#10B981]` · background `[#0A101F]`

**Palette rule:** the portrait must be a different hue from the UI chrome, or the face blends into its own frame.

## PHASE 1 — Banner (dark.svg / light.svg)

One terminal window, **1180×610**, titled `profile.sh --live`. Left ~38% is a portrait frame labelled `VISUAL.MAP`. Right is a `SYSTEM.INFO` readout with dotted leaders, a pulsing red LIVE badge, and a coloured pill with my handle.

### Portrait — build this in Python

- Crop **head + shoulders**, not a tight face crop (over-zoomed reads aggressive)
- **300×340** grid, then **1-bit Floyd-Steinberg dither, serpentine order**
- Contrast **1.3× only**, with `autocontrast(cutoff=1)` + `UnsharpMask(radius=3, percent=140)`
- Draw dots as `<path>` runs with `shape-rendering="crispEdges"` — never font glyphs, they mush below ~2px
- **Dark mode:** segment the background out (threshold on colour distance, binary closing, fill holes, keep largest component) so dots draw the lit subject on the panel. Hard-clear error-diffusion bleed at the mask edge. Without this, dark mode looks like a photo negative
- **Light mode:** keep the background; dots draw the dark parts of the photo
- Single hue — all tone from dot density
- **No** grid lines, scanlines, glitch bars, or CRT flicker

### Animation

**Intro (~3.2s, once):** ~60 **interleaved random** groups fade in over ~2s. Each group must be scattered across the *whole* portrait so dots appear everywhere at once and thicken together. Do **not** use a wipe. Do **not** group by spatial region — that reveals patch-by-patch instead of shimmering in. Verify with an evenness metric (~0.05 good, ~0.7 patchy). Needs a duplicate portrait layer (~180KB); merging to one layer breaks it.

**Loop (~14.2s):** portrait 3.0s, each logo 2.0s, 1.3s transitions. Use **explicit uneven** `keyTimes` — evenly-spaced keyframes force every phase to hold the same length.

### Two independent layers:

1. **Portrait** — full density (~17k dots), grouped into ~94 drift bands. On the loop each band translates ~42% toward the first logo's centroid while fading, then returns
2. **Travellers** — ~900 dots that morph between logos, matched by optimal transport so each takes the shortest path. Opacity keyframes `0;0;0;1;1;...;0` so they're **hidden during the portrait phase** — otherwise their thicker dots crowd the fine dither

**The trap that will bite you:** drift is a *linear* function of position, so quantizing it into groups mathematically recreates a square grid — and the dissolve looks blocky. Add per-dot noise (sigma ~4) before grouping. Verify with a straight-boundary metric: ~0.01 organic, ~0.17 means you built a grid.

## Info panel

- Rows at **font-size 14**, header 13, LIVE 12, pill 14, spacing 23px
- Lock every row with `textLength` + `lengthAdjust="spacingAndGlyphs"` so values stay right-aligned in any browser font
- Dotted leaders computed from label/value length — never hand-edit the SVG

Rows: Subject, Role, Origin, Education, Status, ToolChain · Core.Lang, Core.Frontend, Core.Backend, Core.Database, Core.Infra · Grid.Mail, Grid.Portfolio, Grid.Linkedin, Grid.GitHub, Grid.Facebook

## PHASE 2 — Stats cards (self-hosted)

Walk me through **self-hosting** github-readme-stats — don't just hand me public-instance URLs. The public instance is shared by thousands and constantly returns "API rate limit exceeded". Give me these steps explicitly:

1. Create a GitHub **classic token**: Settings, Developer settings, Tokens (classic), Generate new (classic), `repo` scope, **No expiration**. Warn me to copy it immediately and never paste it anywhere public
2. Fork `anuraghazra/github-readme-stats`
3. Vercel, sign up with GitHub, Hobby (free), Add New Project, import the fork
4. Add environment variable `PAT_1` = my token, then Deploy
5. Ask me for my instance URL, then generate the themed block

Then produce: a streak card (streak-stats.demolab.com) at `width="100%"`, plus stats and top-langs side by side at `width="49%"`. Theme everything to my palette. Include `hide_rank=true` — the rank is stars-weighted and misleading for newer accounts. Explain why rather than just doing it.

## PHASE 3 — Contribution snake

Write me `.github/workflows/snake.yml` using `Platane/snk/svg-only@v3`, on a 12-hour cron plus `workflow_dispatch` plus push to main, pushing to an `output` branch via `crazy-max/ghaction-github-pages@v3.1.0`. Include `permissions: contents: write`.

Tell me to set repo **Settings, Actions, General, Workflow permissions, Read and write**, and be explicit that this is the *repo's* settings, not my account settings.

Two output SVGs — light and dark — themed to my palette. **The first colour in `color_dots` is the empty cell.** For the dark snake it must be a visible slate like `#2d3343`: against GitHub's `#0d1117` background a near-black empty cell disappears and the grid looks broken. Display via a theme-aware `<picture>`, and tell me to only add it *after* the Action runs green — the `output` branch doesn't exist before then.

## PHASE 4 — Social badges

shields.io badges, `for-the-badge` style, my background colour, `&nbsp;&nbsp;` between each, all clickable.

**Warn me about the LinkedIn bug:** its logo only renders on brand blue `#0A66C2`. On any custom colour the glyph silently vanishes, leaving just text. Either use brand blue or embed the glyph as a base64 data-URI to keep it themed. Other logos (Instagram, Gmail, Facebook) recolour fine.

Skip a GitHub badge — it's circular on my own profile.

### FINALLY — assemble

Give me the complete README in one block: banner `<picture>`, then stats, then snake, then badges, with every `USERNAME` filled in. Then a short checklist of what I do by hand (upload SVGs, create the token, deploy Vercel, enable Actions permissions).

### How to work with me

- **Verify by measurement, not by eye.** `cairosvg` renders only the first SMIL frame and mishandles additive transforms and `textLength`. Use correlation vs the approved render, band distributions, ink coverage — then tell me to check in a browser
- **When I say something "didn't change,"** check the file first:  
`raw.githubusercontent.com/.../file.svg?v=999`, view-source, search the hex. It's almost always CDN cache, not a bug. Also check I'm in the right theme — dark assets only render in dark mode
- **Flag file size honestly.** The banner lands ~900KB–1MB. Warn me before expensive changes
- **Tell me when I'm wrong.** If an idea won't work or costs more than it's worth, say so instead of building it
- **If I reject something twice, stop and ask** rather than trying a third variation
- Keep the generator script and `.npy` data — they're the source of truth, not the SVG

▲ END OF PROMPT ▲

## What to expect

### Phase by phase

| Phase      | Effort  | Iteration?                          |
|------------|---------|-------------------------------------|
| 1 — Banner | 1-2 hrs | <b>Yes</b> — contrast, crop, timing |
| 2 — Stats  | 20 min  | No — config only                    |
| 3 — Snake  | 10 min  | No — config only                    |
| 4 — Badges | 5 min   | No — config only                    |

Phase 1 is the whole project. Phases 2-4 are copy-paste and could be done without AI at all — they're in the prompt so you get one continuous session instead of switching documents.

### Known issue: 1080p moiré

At GitHub's ~900px README width the dot lattice sits near 1 dot per screen pixel and can produce faint vertical banding. It vanishes when you zoom. Already tried and rejected:

| Attempt                        | Result                                        |
|--------------------------------|-----------------------------------------------|
| Remove <code>crispEdges</code> | –40% banding, still visible; softens portrait |
| Cap run lengths                | No measurable effect                          |
| Per-dot jitter                 | Helps slightly; file balloons to 2.8MB        |
| Shorter dots (0.75–0.85)       | –12-25%; portrait correlation 1.0 to 0.90     |

The only real fix is fewer, larger dots — a coarser portrait. Most visitors never notice. Don't burn hours here.

### Approaches that already failed

- **Bayer / ordered dithering** — too chunky, loses facial detail
- **2.4× contrast** — harsh and skull-like. A moody reference photo's look comes from its *lighting*, not its dithering
- **Tight face crop** — reads aggressive; head-and-shoulders is friendlier
- **Full-swarm morph (1,500 dots)** — portrait becomes a loose impression
- **Signature-grouped morph** — shapes rendered at 23–52% accuracy, 831KB
- **Convergence clustering** — produced blocky tiles (the grid trap)
- **ASCII / character portrait** — glyphs mush at small sizes

## The core tradeoff

Portrait quality comes from ~17,000 dots. Living per-dot motion requires ~1,000. **These are incompatible in one SVG.** The two-layer design is the resolution: a dense portrait that dissolves, plus a sparse swarm that travels. If you ask for both at once, that's the wall you'll hit.

**If you only want stats, snake, and badges** — skip this document entirely. Those need no AI and no Python. The companion **Setup Guide** is 45 minutes of copy-paste and covers them with full troubleshooting.
